lme4 extras

Ben Bolker

March 8, 2012

This vignette is intended to document some extra tricks that can be used with `lme4` models. Some of them are included here because they are statistically non-rigorous and we didn't want to build them into automatic functions that could be applied unthinkingly, but recipes are supplied here for use **at your own risk** and assuming that you know what you're doing ...

1 Fit basic models

```
library(lme4Eigen)
fm1 <- lmer(Reaction ~ Days + (Days|Subject), sleepstudy)
gm1 <- glmer(cbind(incidence, size - incidence) ~ period + (1 |
herd),
                    data = cbpp, family = binomial)
```

2 Quadratic confidence intervals on random effects parameters

Extract the deviance function and the ML (or REML) parameters:

```
fm1Fun <- update(fm1,devFunOnly=TRUE)
fm1_par <- getME(fm1,"theta")
```

FIXME: In order to compute quadratic approx. of variances or standard deviations, need function to translate from var-cov or sd-cor vector *to* theta vector (i.e., do the Cholesky decomposition) ...

Use the `numDeriv` package to compute the Hessian (second derivative) matrix at the MLE:

```
library(numDeriv)
h <- hessian(fm1Fun,fm1_par)
```

Variance-covariance matrix of the random-effects (Cholesky) parameters:

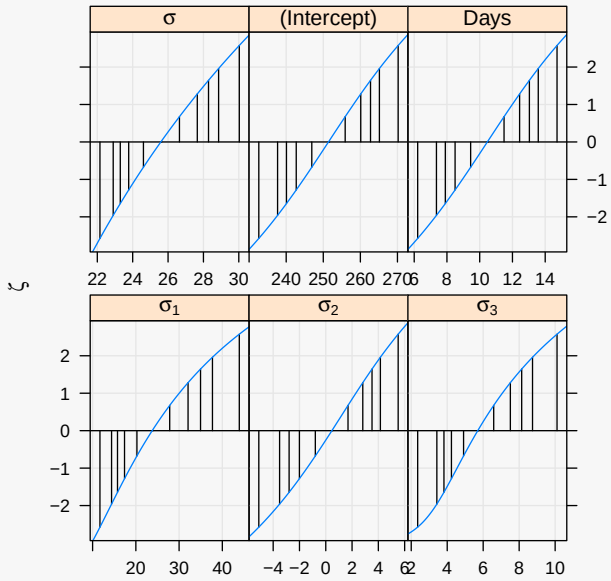
```
(vcov_ran <- solve(h))
```

```
##             [,1]       [,2]       [,3]
## [1,]  0.0288262 -0.0022485  0.0009063
## [2,] -0.0022485  0.0027708 -0.0005797
## [3,]  0.0009063 -0.0005797  0.0013941
```

Compare profiles to their quadratic approximations, and profile confidence intervals to these approximate (Wald) confidence intervals:

```
pp <- profile(fm1)
```

```
xyplot(pp)
```



```
## subset(pp,.par %in% c(".sig01",".sig02",".sig03"))
library(plyr)
```

```
ci_prof <- confint(pp)[1:3,]
```

3 Approximate confidence intervals on predictions

Recipe for getting confidence intervals on predictions, ignoring uncertainty of random-effects parameters:

4 Poor man's MCMC

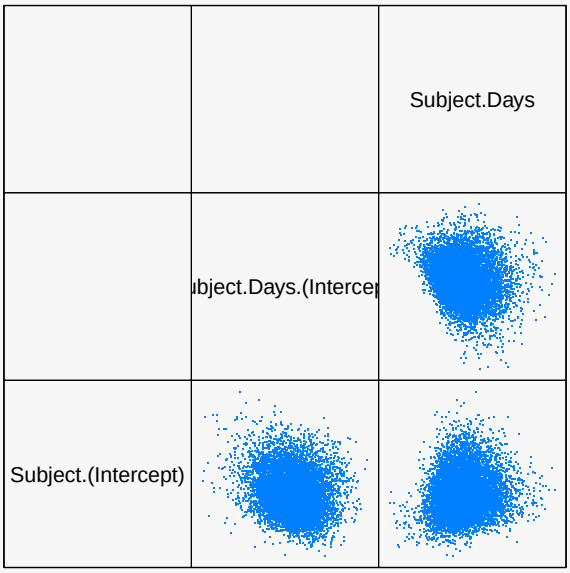
```
library(MCMCpack)
```

`MCMCpack` expects a function that gives a value proportional to the log posterior density for any specified set of parameters. We can get `lme4` to give us a function for the deviance (by using `devFunOnly=TRUE`. If we assume all-improper priors (i.e. flat on the scale on which we have defined the parameters), then the log posterior density is $-D/2$:

```
fm1_metropfun <- function(x) {
  ## getME(.,"lower")?
  if (any(x<fm1@lower)) -Inf else -fm1Fun(x)/2
}
```

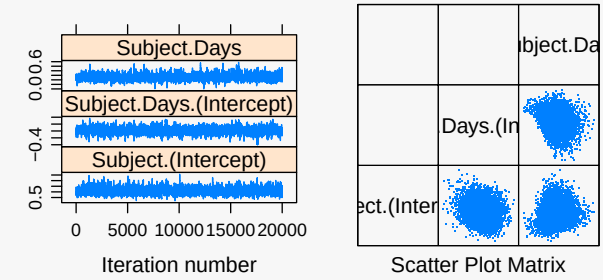
```
fm1_mcmc_out <- MCMCmetrop1R(fm1_metropfun,fm1_par,seed=12345)
colnames(fm1_mcmc_out) <- names(fm1_par)
```

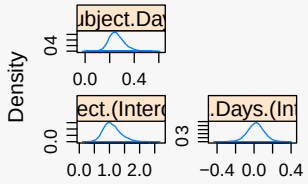
```
library(coda)
library(scapeMCMC)
library(gridExtra)
splom(fm1_mcmc_out)
```



Scatter Plot Matrix

```
grid.arrange(xyplot(fm1_mcmc_out),
             splom(fm1_mcmc_out),
             densityplot(fm1_mcmc_out,layout=c(2,2)),
             ncol=2)
```





```
HPDinterval(fm1_mcmc_out)
```

```
##                               lower  upper
## Subject.(Intercept)          0.5646 1.6712
## Subject.Days.(Intercept) -0.1693 0.1903
## Subject.Days                 0.1416 0.3966
## attr(,"Probability")
## [1] 0.95
```

Translate

```
sdmat <- as.mcmc(t(apply(fm1_mcmc_out,1,
                         function(x)
VC(fm1,theta=x,format="sdcorvec"))))
```

Highest posterior density intervals:

```
HPDinterval(sdmat)
```

```
##                               lower   upper
## Subject.(Intercept)          14.4493 42.7685
## Subject.Days.(Intercept) -0.5457  0.6567
## Subject.Days                  4.0532 10.5283
## attr(,"Probability")
## [1] 0.95
```

Or quantile-based estimates:

```
t(apply(sdmat,2,quantile,c(0.025,0.975)))
```

```
##                               2.5%   97.5%
## Subject.(Intercept)      15.4823 44.2549
## Subject.Days.(Intercept) -0.5194  0.6922
## Subject.Days              4.2457 10.8785
```

The latter *should* be translation-invariant, and hence (???) the same as:

```
qq <- t(apply(fm1_mcmc_out,2,quantile,c(0.025,0.975)))
apply(qq,2,function(x) VC(fm1,theta=x,format="sdcorvec"))
```

```
##                               2.5%   97.5%
## Subject.(Intercept)      15.4823 44.2549
## Subject.Days.(Intercept) -0.7561  0.4393
## Subject.Days              5.6209 11.4225
```

(Only true for variable 1, although not terribly different: think about this (i.e. the effect of $\theta\theta^T$) some more ...)

If we have the Cholesky form

$$\begin{pmatrix} c_1 & 0 \\ c_2 & c_3 \end{pmatrix}$$

and take the cross-product, we get

$$\begin{pmatrix} c_1^2 & c_1 c_2 \\ c_1 c_2 & c_2^2 + c_3^2 \end{pmatrix}$$

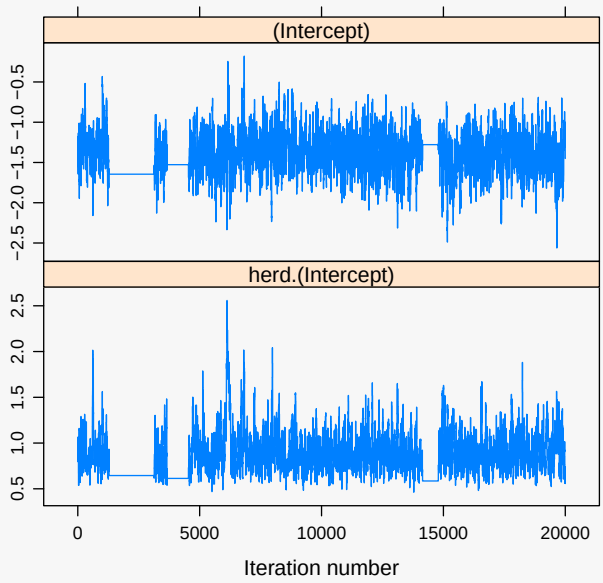
so it's natural that only element 1 scales as we would expect: all the other terms are not just scale translations of a single element, but combinations of multiple elements.

Should work for GLMMs as well:

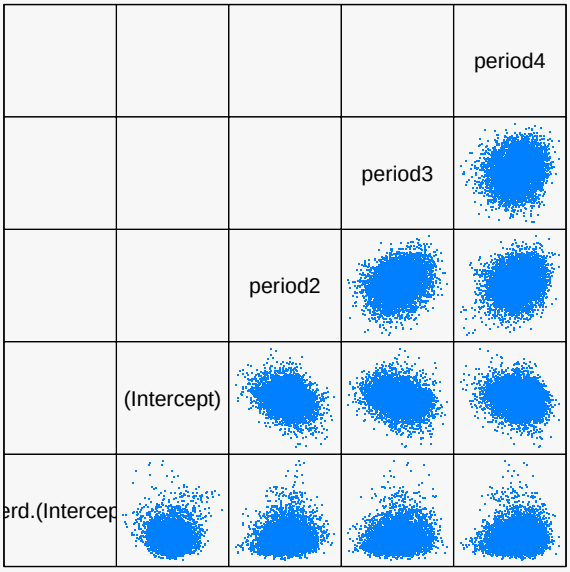
```
gm1Fun <- update(gm1,devFunOnly=TRUE)
gm1_par <- c(getME(gm1,"theta"),fixef(gm1))
nt <- length(getME(gm1,"theta"))
gm1_metropfun <- function(x) {
  if (any(x[seq(nt)]<gm1@lower)) -Inf else -gm1Fun(x)/2
}
```

```
gm1_mcmc_out <- MCMCmetrop1R(gm1_metropfun,gm1_par)
```

```
colnames(gm1_mcmc_out) <- names(gm1_par)
xyplot(gm1_mcmc_out[,1:2])
```



```
splom(gm1_mcmc_out)
```



```
HPDinterval(gm1_mcmc_out)
```

```
##                     lower   upper
## herd.(Intercept)  0.5374  1.3001
## (Intercept)      -1.8677 -0.8982
## period2          -1.6297 -0.4787
## period3          -1.8173 -0.6129
## period4          -2.4901 -0.8896
## attr(,"Probability")
## [1] 0.95
```

5 Confidence intervals on predictions etc. via parametric bootstrap

FIXME: do we want a `as.data.frame.boot` function to retrieve stuff from `bootMer` output?

6 Zero-inflation via the EM algorithm

Adapted from code by Mihoko Minami and Cleridy Lennert (ref??)

```
zipme <- function(cformula, zformula, cfamily=poisson,
                  data, maxitr=20, tol=1e-6, verbose=TRUE) {
  ##   y is the observation from the distribution:
  ##           P(Y=0)=p+(1-p)F(0,lambda)
  ##           P(Y=k)=(1-p)F(k,lambda).
  ##  zformula: formula for logistic regression on
zero-inflation: LHS should be z~
  ##  cformula: formula for Poisson or NB regression. LHS should
be: y~
  ##   maxitr  : maximum number of iterations
  ##   tol: convergence tolerance
  ##

  m<-nrow(data)
  rname <- as.character(cformula)[2]
  ## initialize z and probz (z=1 -> perfect state; probz is
probability of 0 in imperfect state for poisson)

  z<-numeric(m)
  probz<-numeric(m)
  z[data[[rname]]==0]<- 1/(1+exp(-1))  ## starting value
```

```
  ## n.b. we are looking for [3] since zformula has a LHS
  randz <-
length(grep("\\(.*\\|.*\\)",as.character(zformula)[3]))>0
  ## delta is used to gauge convergence. after initialization, it
is the abs. difference between current z and new z.
  itr <- 1
  delta <- 2
  deltainfo <- numeric(maxitr)
  while(delta>tol & itr <= maxitr){
    if (verbose) cat("itr:",itr,"\n")
    ## make (update) working data frame
    bydataw <- data.frame(z=z,data)
    ##
    ## Maximization 1: logistic
    old.z<-z
    if (randz) {
      uu <- glmer(zformula, family=binomial, data=bydataw)
    } else {
      uu <- glm(zformula, family=binomial, data=bydataw)
    }
    ## save current logistic model output
    u <- fitted(uu)
    ##
    ## Maximization 2: poisson/NB loglinear with weights
    vv <- glmer(cformula, family=cfamily, weights=(1-z),
data=bydataw)
    ## save Poisson model output
    v <- fitted(vv)
    ##
    ## Expectation: used to update z with conditional
expectation;only need to update at y=0.
    zdat <- data[[rname]]==0
    z[zdat] <- u[zdat]/( u[zdat]+(1-u[zdat])*exp(-v[zdat]))
    new.z<-z
    ## updated convergence indicator
    delta<-max(abs(old.z-new.z))
    ## save delta for this iteration; to be output
    deltainfo[itr] <- delta
    itr <- itr+1
  }
  L <- list("zfit"=uu, "cfit"=vv, itr=itr, deltainfo=deltainfo,
z=z)
  ##    uu.binom : output object of logistic regression;
  ##    vv.flm   : output object of poisson regression
  class(L) <- "zipme"
```

```
  L
}
```
